The present invention provides a new process for the preparation of 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride, wherein this compound is prepared directly from the chloromethylalcohol. Importantly, the process of the present invention results in higher yields of 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride without sacrificing its purity. The processes of the present invention can be used to prepare not only the 2S,3S-derivative, but also the 2R,3S-, 2S,2R- and the 2R,3R-derivatives.
FIG. 1.
PREPARATION OF 2S,3S-N-ISOBUTYL-N-(2-HYDROXY-3-AMINO-4-PHENYL Butyl)-P-NITROBENZENESULFONYLAMIDE HYDROCHLORIDE AND OTHER DERIVATIVES OF 2-HYDROXY-1,3-DIAMINES

CROSS-REFERENCE TO RELATED APPLICATION

This patent application claims the benefit of U.S. Provisional Patent Application No. 60/172,043, filed Dec. 23, 1999, which is incorporated herein by reference in its entirety for all purposes.

BACKGROUND OF THE INVENTION

Human immunodeficiency virus (HIV), the causative agent of acquired immunodeficiency syndrome (AIDS), belongs to a class of enzymes, including the well-characterized protease belonging to the aspartic proteinase family, the HIV protease. Inhibition of this enzyme has been regarded as a promising approach for treating AIDS. Hydroxysterolamine isosterest have been extensively utilized in the synthesis of potent and selective HIV protease inhibitors. However, this modern generation of HIV protease inhibitors has created an interesting challenge for the synthetic organic chemist. Advanced x-ray structural analysis has allowed for the design of molecules that fit closely into active sites on enzymes creating very effective drug molecules. Unfortunately, these molecules, designed by molecular shape, are often difficult to produce using conventional chemistry.

The modern generation of HIV inhibitors has structural similarities in a central three-carbon piece containing two chiral carbons that link two larger groups on each side (see, e.g., Parkes, et al, J. Org. Chem., 59:3656 (1994)). In general, the chemical bond from the central part to one of the larger groups is a carbon-nitrogen bond which is usually accomplished by reacting an epoxide with an amine. 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride is a key intermediate in the synthesis of protease inhibitors (see, e.g., U.S. Pat. Nos. 5,585,397, 5,723,490 and 5,783,701 as well as PCT International Publication No. WO 94/0563, the teachings of all of which are incorporated herein by reference). The process currently used to prepare 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride is illustrated in FIG. 1.

As illustrated in FIG. 1, 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride is prepared by a 4-step process starting from a commercially available (Aerojet Fine Chemicals (Sacramento, Calif.)) starting material, 2S,3S-chloromethylalcohol (2S,3S-CMA). In the first step, 2S,3S-CMA is reacted with sodium hydroxide in THF/ethanol to give the corresponding epoxide in 91% yield. In the second step, the epoxide is dissolved in toluene and reacted with excess isobutylamine at a temperature of about 75° C. to about 80° C. to give Compound I. Reaction of Compound I with p-nitrobenzenesulfonyl chloride (i.e., nosyl chloride) in toluene at a temperature of about 85° C. to about 90° C., followed by deprotecting of the Boc protecting group with aqueous HCl at a temperature of about 85° C. to about 90° C. gives Compound III, i.e., 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride, in 64% overall yield.

Unfortuantly, this process has a number of drawbacks. Some of the drawbacks associated with this process include high reaction temperatures which lead to the formation of side products; low solubility of intermediates in the reaction solvent which requires high processing temperatures during work-up; which, in turn, leads to longer cycle times, material handling losses, etc.; and the like. As such, there remains a need in the art for an improved process for preparing 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride which overcomes the drawbacks associated with the currently used process. Quite surprisingly, the present invention fulfills this and other needs.

SUMMARY OF THE INVENTION

The present invention provides a new process for the preparation of 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride, i.e., Compound III. In this new process, one of the chemical steps (i.e., the epoxide step) as well as material handling losses associated with the previously used process have been eliminated. More particularly, using the process of the present invention, the chloromethylalcohol, i.e., HMA, (e.g., chloromethylalcohol) is successfully converted to Compound III directly without the need to isolate the Boc-epoxide. Numerous publications have described the synthesis of Compound I-like materials, but they all involve reaction of an epoxide with an amine. As such, the process of the present invention is the first example of a process wherein a protease inhibitor intermediate is prepared directly from the chloromethylalcohol. Moreover, the process of the present invention results in a higher yield of Compound III, while not sacrificing its purity. In addition, the process of the present invention allows for the use of the lower purity HMA, thereby eliminating a purification step. Finally, it is pointed out that elimination of the epoxide step eliminates the need to isolate a toxic intermediate (i.e., a mutagen) and, thus, circumvents safety issues involved with dust explosivity of the Boc-epoxide.

Other features, objects and advantages of the invention and its preferred embodiments will become apparent from the detailed description which follows.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates the process previously used to prepare 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride.

DESCRIPTION OF THE INVENTION AND PREFERRED EMBODIMENTS

It has now been discovered that a protease inhibitor intermediate, i.e., 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride, can be prepared directly from a chloromethylalcohol (HMA) (e.g., chloromethylalcohol) without having to isolate the Boc-epoxide. As such, the present invention provides a new process for the preparation of 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride, i.e., Compound III, wherein this compound is prepared directly from a HMA. Importantly, the process of the present invention results in higher yields of Compound III, while not sacrificing its purity. Moreover, the process of the present invention can be used to prepare not only the 2S,3S-derivative, but also the 2R,3S-, 2S,3R- and the 2R,3R-derivatives.

As such, the first step in the process for preparing a Compound of Formula III involves the preparation of a
compound having the following general formula:

\[
\begin{align*}
R^1 & \text{HN} \\
& \text{OH} \\
& \text{X} \\
R^2 & \text{NH} \\
& \text{OH}
\end{align*}
\]

the process comprising: combining a halomethylalcohol, e.g., chloromethylalcohol, with an amine, e.g., isobutylamine (IBA), to form a reaction mixture, and heating the reaction mixture until the reaction is complete, thereby forming the compound of Formula I, wherein the HMA has the following general formula:

\[
\begin{align*}
R^1 & \text{HN} \\
& \text{OH} \\
& \text{X} \\
R^2 & \text{NH} \\
& \text{OH}
\end{align*}
\]

In the above process, X is a leaving group (e.g., a halo group, such as chloro, bromo, fluoro or iodo, a tosylate group, a mesylate group, etc.); \( R^1 \) is an amino acid side chain or a functionalized amino acid side chain (e.g., an alkyl group, a benzyl group, a phenyl thiomethyl group, a protected hydroxymethyl group, an S-alkyl group, a nitrobenzenyl group, etc.); \( R^2 \) is a protecting group (e.g., t-Boc (tert-butyloxycarboxy), i-Boc (iso-butyloxycarboxy),Cbz (benzyloxycarboxy), MOC (methoxycarboxy), Fmoc (fluorenylmethoxycarbony), dibenzyl, etc.); and \( R^2 \) and \( R^4 \) are independently selected and are functional groups including, but not limited to, hydrogen, alkyl, cycloalkyl, aryl and -NHP, wherein P is selected from the group consisting of \( H \), alkyl, cycloalkyl, aryl and a protecting group or, alternatively, \( R^3 \) and \( R^4 \) together can form a cyclic structure including, but not limited to, quinoline and isoquinoline, etc.

In a preferred embodiment, the HMA is a 2S,3S-halomethylalcohol (2S,3S-HMA). In a presently preferred embodiment, the 2S,3S-HMA has the following formula:

\[
\begin{align*}
& \text{OH} \\
t-\text{Boc} \text{HN} \\
& \text{Cl}
\end{align*}
\]

In another preferred embodiment, the Compound of Formula I has the following formula:

\[
\begin{align*}
& \text{OH} \\
t-\text{Boc} \text{HN} \\
& \text{Cl}
\end{align*}
\]

In the above process, a HMA is reacted with an amine at a temperature ranging from about 50° C. to 100° C. to give the compound of Formula I in high yields. In a presently preferred embodiment, the HMA is reacted with an amine at a temperature ranging from about 60° C. to about 75° C. to give the Compound of Formula I in very high yields (about 98–99% yield). The amine used in the above process can be a primary amine, a secondary amine, a substituted amine (e.g., N-substituted sulfonamides, etc.), hydrazines and substituted hydrazines (e.g., N-substituted hydrazine, etc.). Exemplar amines include, but are not limited to, methylamine, ethylamine, isopropylamine, n-butylamine, isobutylamine, cyclohexylamine, benzylamine, para-nitrobenzylamine, dimethylamine, isobutylmethylamine, decahydroquinoline, decahydroisoquinoline, pyrimidine, isobutylparanitrobenzenesulfonamide, methylparanitrobenzenesulfonamide, isobutylmethylparanitrobenzenesulfonamide, hydrazine, substituted hydrazines, etc.

In a presently preferred embodiment, the amine employed in the above process is isobutylamine (IBA). Importantly, the solvent employed in the previously used method (i.e., toluene) has been eliminated and, in this embodiment, the reaction is conducted in neat IBA, using IBA as the reaction solvent. This simplifies the IBA recovery process (no fractional distillation/column needed to separate IBA from toluene), and allows for the reaction to be carried out at slightly lower temperatures. It has been found, however, that under these conditions, the reaction times can be relatively long (~30 h). To reduce reaction times, it has been discovered that an acid scavenger can be added to the reaction mixture.

As such, in one embodiment of the above process, an acid scavenger is added to the reaction mixture to reduce reaction times. In a preferred embodiment, the acid scavenger has the general formula: \( M^+B^- \), wherein \( M^+ \) is selected from the group consisting of \( K^+, Na^+, Li^+, Ca^{2+}, Mg^{2+} \) and \( Al^{3+} \); and \( B^- \) is selected from the group consisting of \( OH^-, HCO_3^- \) and \( CO_3^{2-} \). In a preferred embodiment, the acid scavenger is sodium bicarbonate. In another preferred embodiment, the acid scavenger is potassium bicarbonate. When an acid scavenger is added to the reaction mixture, about 0.5 to 2 equivalents are added. In a presently preferred embodiment, about 1 equivalent of the acid scavenger is added to the reaction mixture. It has been found that by adding even only 1.05 equivalents of an acid scavenger (e.g., sodium bicarbonate) to the reaction mixture, the reaction times can be reduced from 30 hours to less than 4 hours. Moreover, this reduction in reaction times can be achieved without sacrificing product quality and/or yield. It will be readily apparent to those of skill in the art that other acid scavengers, base phosphates, etc. can be used in the methods of the present invention to reduce reaction times.

Thus, as illustrated in Table I, the reaction rates of the base catalyzed reaction of chloromethylalcohol (CMA) with
isobutyl amine are comparable to those of the epoxide with isobutyl amine, with the reaction being substantially complete in 3 hours.

Moreover, it is pointed out that the Boc-epoxide employed in the previously used method is thermally unstable, and at higher temperatures (>70°C) will undergo a deprotecting reaction to give free amine which, in turn, leads to a variety of side-reactions. In contrast, HMA, e.g., CMA, is more thermally stable than Boc-epoxide. The higher thermal stability of HMA, e.g., CMA, coupled with lower reaction/processing temperatures allows for Compound III to be prepared in a much higher yield and purity. Moreover, using the above process, the purity of isolated Compound I is in the neighborhood of 98.7 to 98.8% (area %) by HPLC. Typical results for the reaction of 2S,3S-CMA with isobutylamine to give Compound I are illustrated below:

In one embodiment, the above process further comprises recovering (e.g., isolating and purifying) the Compound of Formula I from the reaction mixture. However, in a presently preferred embodiment, the Compound of Formula I is filtered and used in the next step without first being purified.

The second step in the process for preparing a Compound of Formula III involves the preparation of a compound having the following general formula:

In the first step of the above process, nosyl chloride is combined with an alkyl acetate to form a first reaction mixture. Alkyl acetates suitable for use include, but are not limited to, methyl acetate, ethyl acetate, isopropyl acetate, isobutyl acetate, etc. In a presently preferred embodiment, ethyl acetate is employed. In the second step of the above process, a tertiary amine is combined with a Compound of Formula I in an aromatic solvent to form a second reaction mixture. Exemplar tertiary amines include, but are not limited to, triethylamine, diisopropylethylamine, pyridine and N-methylmorpholine. In a presently preferred embodiment, triethylamine is used. Suitable aromatic solvents, include, but are not limited to, toluene, benzene and xylene. In a presently preferred embodiment, toluene is used. In the third step of the above process, the first reaction mixture is added to the second reaction mixture to form a third reaction mixture, and the third reaction mixture is
heated until the reaction is complete. In a presently preferred embodiment, the first reaction mixture is heated or warmed prior to adding it to the second reaction mixture. The third reaction mixture is heated to a temperature ranging from about 50°C to about 100°C and, more preferably, to a temperature ranging from about 60°C to about 75°C.

Ethyl acetate is a good solvent for Compound I and Compound II intermediates; however, under certain conditions, Compound I will react with ethyl acetate to give N-acetyl Compound I. As such, it has now been surprisingly discovered that the best way to carry out the above process, i.e., the second step in the preparation of the Compound of Formula III, is to dissolve the nosyl chloride in ethyl acetate (nosyl chloride is not very soluble in toluene), and then add it to a solution of the Compound of Formula I in toluene that has been warmed to a temperature of about 70°C. Under these conditions, the reaction is instantaneous and is complete when the addition is done. Moreover, since nosyl chloride is much more reactive than ethyl acetate, formation of the N-acetyl Compound I is not detected. Further, addition of ethyl acetate to the reaction mixture improves the solubility of Compound II in the reaction mixture, thereby allowing the processing to be conducted at about 70°C instead of at about 85°C. Use of ethyl acetate as a co-solvent also improves the partitioning of the Compound of Formula II into the organic phase and, thus, minimizes loss due to product loss in aqueous phase. Further, use of lower reaction temperature (70°C versus 85–90°C) also improves the quality of the Compound of Formula II since side reactions, such as de-protecting, etc., are minimized at lower temperatures.

In an alternative embodiment, the Compound of Formula II can be prepared directly from a HMA. As such, the present invention provides a process for the preparation of a compound having the general formula:

\[
\text{II} \quad \text{R}^1 \quad \text{R}^2 \quad \text{R}^3 \quad \text{R}^4 \quad \text{X}
\]

the process comprising: combining a halomethyl alcohol (HMA) with a sulfonamide to form a reaction mixture, and heating said reaction mixture until the reaction is complete, thereby forming the compound of Formula II, wherein said HMA has the following general formula:

In the above process, R\(^1\) is an amino acid side chain or a functionalized amino acid side chain; R\(^2\) is a protecting group; R\(^3\) is a functional group including, but not limited to, hydrogen, alkyl, cycloalkyl, aryl and —NHP, wherein P is selected from the group consisting of H, alkyl, cycloalkyl, aryl and a protecting group; R\(^4\) is a functional group including, but not limited to, alkyl, cycloalkyl and aryl; and X is a leaving group.

In a preferred embodiment, the HMA is a 2S,3S-halomethyl-alcohol (2S,3-HMA). In a presently preferred embodiment, the 2S,3S-HMA has the following formula:

In the above process, the HMA is reacted with a sulfonamide. Suitable sulfonamides include those having the following general formula:

\[
\text{H} - \text{N} - \text{R}^5
\]

wherein: R\(^5\) and R\(^6\) are independently selected and are functional groups including, but not limited to, alkyl, cycloalkyl and aryl.

In one embodiment of the above process, an acid scavenger can be added to the reaction mixture to reduce reaction times. In a preferred embodiment, the acid scavenger has the general formula: M\(^+\)B\(^-\), wherein M\(^+\) is selected from the group consisting of K\(^+\), Na\(^+\), Li\(^+\), Ca\(^{2+}\), Mg\(^{2+}\) and Al\(^{3+}\); and B\(^-\) is selected from the group consisting of —OH, HCO\(_3\)\(^-\) and CO\(_3\)\(^{2-}\). In a preferred embodiment, the acid scavenger is sodium bicarbonate. In another preferred embodiment, the acid scavenger is potassium bicarbonate. When an acid scavenger is added to the reaction mixture, about 0.5 to 2 equivalents are added. In a presently preferred embodiment, about 1 equivalent of the acid scavenger is added to the reaction mixture. In this process, a HMA is reacted with a sulfonamide at a temperature ranging from about 50°C to 125°C to give the compound of Formula II in high yields. In a presently preferred embodiment, the HMA is reacted with a sulfonamide at a temperature ranging from about 60°C to about 80°C to give the Compound of Formula II in very high yields.

The final step in the process of the present invention involves the conversion of a Compound of Formula II to a Compound of Formula III, the Compound of Formula III having the following general formula:
In step (b) of the above process, the reaction mixture is treated or contacted with an acid having a pKa of less than about 4. Suitable acids include, but are not limited to, HCl, HBr, CF3CO2H, CF3SO3H, CH3SO3H, H2SO4, citric acid, tartaric acid, oxalic acid and p-toluene sulfonic acid. The reaction mixture is treated with the acid for a time period of at least about 0.5 hours and, typically, for a period of time ranging from about 1 to about 5 hours. In a presently preferred embodiment, the acid is aqueous hydrochloric acid (HCl). In this embodiment, the hydrochloric acid can be, for example, about 37% aqueous hydrochloric acid. In another preferred embodiment, the hydrochloric acid is gaseous hydrochloric acid. In this embodiment, the gaseous hydrochloric acid can be bubbled through the reaction mixture. In another presently preferred embodiment, the acid is methanesulfonic acid (CH3SO3H). In a presently preferred embodiment, the Compound of Formula III is recovered from the reaction mixture.

In addition to the foregoing, it has also been discovered that a halogenated solvent (e.g., methylene chloride) is a superior solvent than toluene or toluene/ethyl acetate for synthesizing the Compounds of Formulae II and III. The higher solubility of Compound I-III intermediates in a halogenated solvent (e.g., methylene chloride) allows for the reactions to be carried out at much lower temperatures (about 30 to 35° C. lower than the toluene/ethyl acetate process and about 45-50° C. lower than the toluene process). The ability to conduct the reactions at lower temperatures has a profound effect on the quality and yield of the resulting material. Low reaction temperatures minimize decomposition and other side-reactions (e.g., deprotecting), thereby leading to products with fewer impurities which, in turn, leads to improved quality and higher yield (15 to 20% higher yield). It has been found that the rate of the deprotecting reaction with, for example, aqueous HCl is much slower in a halogenated solvent (e.g., methylene chloride) than in toluene or toluene/ethyl acetate. For example, in toluene/ethyl acetate the time required to achieve >99% conversion is about 3 hours, whereas in methylene chloride, it is nearly 5 days. However, it has surprisingly been discovered that the use of, for example, gaseous HCl instead of aqueous HCl, will reduce the reaction time from 5 days to 3 hours. An additional advantage for using gaseous HCl is that it does not require additional stripping to remove the water. When HCl is employed as the acid, the final product (Compound III) is a hydrochloride salt, and it is important to remove water in order to achieve a good yield. However, this problem is eliminated when anhydrous gaseous HCl is used. Moreover, the product quality of crude Compound III prepared by the halogenated solvent route is much better than that of crude Compound III prepared by the toluene or toluene/ethyl acetate processes. Consequently, the yield of the isolated Compound III is nearly 15% higher with the halogenated solvent process. In addition, the intermediates do not have to
be isolated when a halogenated solvent (e.g., methylene chloride) is used. It is noted that, e.g. the sulfonamide impurity is soluble in methylene chloride; otherwise, it is very difficult to remove.

As such, in one embodiment, the present invention provides a process for preparing a compound having the following general formula:

\[
\begin{align*}
\text{R}^1 & \text{HN} \quad \text{N} \quad \text{O} \quad \text{NO}_2 \\
\text{OH} & \text{R}^3
\end{align*}
\]

the process comprising: (a) combining nosyl chloride with a halogenated solvent (e.g., methylene chloride) to form a first reaction mixture; (b) combining a tertiary amine (e.g., triethylamine) with a compound of Formula I in a halogenated solvent (e.g., methylene chloride) to form a second reaction mixture, the compound of Formula I having the following general formula:

\[
\begin{align*}
\text{R}^1 & \text{HN} \\
\text{OH} & \text{R}^3\text{R}^4
\end{align*}
\]

and, (c) adding the first reaction mixture to the second reaction mixture to form a third reaction mixture, and heating the third reaction mixture to a temperature ranging from about 10°C to about 50°C and, more preferably, to a temperature ranging from about 30°C to about 35°C until the reaction is complete, thereby forming the compound of Formula II. In a presently preferred embodiment, the first reaction mixture is heated or warmed prior to adding it to the second reaction mixture.

In the above process, \(\text{R}^1\) is an amino acid side chain or a functionalized amino acid side chain; \(\text{R}^2\) is a protecting group; and \(\text{R}^3\) is a functional group including, but not limited to, hydrogen, alkyl, cycloalkyl, aryl and \(-\text{NHP}\), wherein \(\text{P}\) is selected from the group consisting of \(\text{H}\), alkyl, cycloalkyl, aryl and a protecting group.

In a presently preferred embodiment, the Compound of Formula I has the following formula:

\[
\begin{align*}
\text{t-BocHN} & \quad \text{OH} \quad \text{NH}
\end{align*}
\]

In another preferred embodiment, the Compound of Formula II has the following formula:
In the above process, an amine is combined with a halogenated solvent. Suitable amines include, but are not limited to, primary amines, secondary amines, substituted amines, hydrazines and substituted hydrazines. Exemplar amines include, but are not limited to, methylamine, ethylamine, isopropylamine, n-butylamine, isobutylamine, cyclohexylamine, benzylamine, paranitrobenzylamine, dimethylamine, isobutylmethylamine, decahyroquinoline, decahydropyridazine, isobuthlyhydrazine and t-Boc-hydrazine. In a preferred embodiment, the amine is isobutylamine (IBA), preferably neat IBA.

In a presently preferred embodiment, the Halomethyl Alcohol (HMA) has the following general formula:

In step (b) of the above process, the reaction mixture is treated or contacted with an acid having a pKₐ of less than about 4. Exemplar acids include, but are not limited to, HCl, HBr, CF₃CO₂H, CF₃SO₃H, CH₂SO₃H, H₂SO₄, citric acid, tartaric acid, oxalic acid and p-toluene sulfonic acid. The reaction mixture is treated with the acid until the reaction is complete, and, typically, for a time period of at least about 0.5 hours and, more preferably, for a period of time ranging from about 1 to about 5 hours. In one preferred embodiment, the hydrochloric acid is aqueous hydrochloric acid. In this embodiment, the hydrochloric acid can be, for example, about 37% aqueous hydrochloric acid. In another preferred embodiment, the hydrochloric acid is gaseous hydrochloric acid. In this embodiment, the gaseous hydrochloric acid can be bubbled through the reaction mixture. In another preferred embodiment, the acid is methanesulfonic acid (CH₃SO₃H). In a presently preferred embodiment, the Compound of Formula III is recovered from the reaction mixture.

In another embodiment, the present invention provides a process for preparing a Compound of Formula III from a HMA, the Compound of Formula III having the following general formula:

In the above process, an amine is combined with a halogenated solvent. Suitable amines include, but are not limited to, primary amines, secondary amines, substituted amines, hydrazines and substituted hydrazines. Exemplar amines include, but are not limited to, methylamine, ethylamine, isopropylamine, n-butylamine, isobutylamine, cyclohexylamine, benzylamine, paranitrobenzylamine, dimethylamine, isobutylmethylamine, decahyroquinoline, decahydropyridazine, isobuthlyhydrazine and t-Boc-hydrazine. In a preferred embodiment, the amine is a primary amine. In a presently preferred embodiment, the amine is isobutylamine (IBA), preferably neat IBA. In the above process, a halogenated solvent is employed. Exemplar halogenated solvents includes, but are not limited to, the following: methylene chloride, chloroform, trifluorotoluene (oxsol), parachlorotrifluorotoluene and trichloroethylene. In a presently preferred embodiment, the halogenated solvent is methyl chloride.

In step (c) of the above process, the solution from step (b) is treated or contacted with an acid having a pKₐ of less than about 4 until the reaction is complete, thereby forming the compound of Formula III.

In the above process, R¹ is an amino acid side chain or a functionalized amino acid side chain; R² is a protecting group; R³ is a functional group including, but not limited to, hydrogen, alkyl, cycloalkyl, aryl and —NHP, wherein P is selected from the group consisting of H, alkyl, cycloalkyl, aryl and a protecting group; and L is a leaving group.

In a presently preferred embodiment, the Compound of Formula III has the following general formula:
In the above process, a tertiary amine is combined with a halogenated solvent. Suitable tertiary amines include, but are not limited to, triethylamine, diisopropylethylamine, pyridine and N-methylmorpholine. In a presently preferred embodiment, triethylamine is used. Exemplar halogenated solvents includes, but are not limited to, the following: methylene chloride, chloroform, trifluorotoluene (oxsol), parachlorotrifluorotoluene and trichloroethylene. In a presently preferred embodiment, the halogenated solvent is methylene chloride.

In step (b) of the above process, the reaction mixture is reacted with an acid having a \( pK_a \) of less than about 4. Exemplar acids include, but are not limited to, HCl, HBr, \( CF_3 CO_2 H \), \( CF_3 S0_3 H \), \( CH_3 S0_3 H \), \( H_2 S0_4 \), citric acid, tartaric acid, oxalic acid and p-toluene sulfonic acid. The solution is treated with the acid until the reaction is complete. Typically, the solution is treated for a time period of at least about 0.5 hours and, more preferably, for a time period ranging from about 1 to about 5 hours. In a preferred embodiment, the acid is hydrochloric acid. In another preferred embodiment, the acid is methanesulfonic acid (\( CH_3 S0_3 H \)).

In yet another embodiment, the present invention provides a process for preparing a Compound of Formula III from a compound of Formula I. The Compound of Formula III has the following general formula:

\[
\text{III}
\]

the process comprising: (a) adding a Compound of Formula I in a halogenated solvent (e.g., methylene chloride) with a tertiary amine and nosyl chloride to form a reaction mixture, and heating the reaction mixture at a temperature ranging from about 10°C to about 50°C and, more preferably, to a temperature ranging from about 30°C to about 35°C; the compound of Formula I having the following general formula:

\[
\text{I}
\]

and (b) reacting the reaction mixture with an acid having a \( pK_a \) of less than about 4 until the reaction is complete, thereby forming the Compound of Formula III.

In the above process, \( R_1 \) is an amino acid side chain or a functionalized amino acid side chain; \( R_2 \) is a protecting group; and \( R_3 \) is a member selected from the group consisting of hydrogen, alkyl, cycloalkyl, aryl and -NHP, wherein \( P \) is selected from the group consisting of H alkyl, cycloalkyl, aryl and a protecting group; and \( X^- \) is the conjugate base of the acid used in step (b).

In a presently preferred embodiment, the Compound of Formula I has the following formula:

\[
\text{I}
\]

In another preferred embodiment, the Compound of Formula III has the following formula:

\[
\text{III}
\]

In the above process, a tertiary amine is combined with a halogenated solvent. Suitable tertiary amines include, but are not limited to, triethylamine, disopropylethylamine, pyridine and N-methylmorpholine. In a presently preferred embodiment, triethylamine is used. Exemplar halogenated solvents include, but are not limited to, the following: methylene chloride, chloroform, trifluorotoluene (oxsol), parachlorotrifluorotoluene and trichloroethylene. In a presently preferred embodiment, the halogenated solvent is methylene chloride.

In step (b) of the above process, the reaction mixture is reacted with an acid having a \( pK_a \) of less than about 4. Exemplar acids include, but are not limited to, HCl, HBr, \( CF_3 CO_2 H \), \( CF_3 S0_3 H \), \( CH_3 S0_3 H \), \( H_2 S0_4 \), citric acid, tartaric acid, oxalic acid and p-toluene sulfonic acid. The solution is treated with the acid until the reaction is complete. Typically, the solution is treated for a time period of at least about 0.5 hours and, more preferably, for a time period ranging from about 1 to about 5 hours. In one preferred embodiment, the acid is hydrochloric acid. In another preferred embodiment, the acid is methanesulfonic acid (\( CH_3 S0_3 H \)).

In a presently preferred embodiment, the process further comprises washing the reaction mixture; heating the reaction mixture to a temperature ranging from about 40°C to about 45°C; and then azeotropically drying the reaction mixture prior to step (b). In another preferred embodiment, the Compound of Formula III is recovered from the reaction mixture. In one such embodiment, the recovery step comprises: (i) cooling the reaction mixture to a temperature of about 5°C; (ii) filtering the reaction mixture to remove the N-isobutyl-p-nitrobenzenesulfonamide impurities and provide the compound of Formula III; and (iii) washing the compound of Formula III and then drying it in vacuo.

Using the above processes, 2S,3S-N-isobutyl-N-(2-hydroxy-3-amino-4-phenylbutyl)-p-nitrobenzenesulfonylamide hydrochloride can be prepared directly from the chloromethylalcohol (CMA) without having to isolate the Boc-epoxide. The process of the present invention is the first demonstration of a process wherein a protease inhibitor intermediate is prepared directly from the halomethylalcohol. Again, this is extremely helpful because elimination of the epoxide eliminates the need to isolate a toxic intermediate (i.e., a mutagen) and, thus, circumvents safety issues involved with dust explosivity of the Boc-epoxide. Importantly, the process of the present invention results in higher yields of Compound III, while not sacrificing its purity.

Those of skill in the art will readily understand that the term “alkyl,” as used herein, refers to a branched or unbranched, saturated or unsaturated, monovalent hydrocarbon radical having from 1–12 carbons and, preferably, from 1–6 carbons. When the alkyl group has from 1–6 carbon atoms, it is referred to as a “lower alkyl.” Suitable alkyl
Additional water (500 g) is added and the product is isolated which are fused together, linked covalently, or linked to a substituent which would otherwise be occupied by a hydrogen atom. The yields normally range in the neighborhood of 97 to 98%. The isolated product was characterized by 1H/13C NMR and by HPLC/TLC analysis.

**B. Preparation of Compound II**

Solution of Compound I in toluene was warmed to 70°C and treated with triethylamine (220 g, 2.18 mol). Then, a solution of p-nitrobenzenesulfonyl chloride (195 g, 0.88 mol) in ethyl acetate (1 L) was added over 3 h. The organic mixture was then washed sequentially at 65–70°C with water (400 mL), 5% aqueous sodium hydrogen carbonate (400 mL) and water (400 mL). The product is obtained as a solution in toluene/ethyl acetate and is used directly in synthesis of Compound III. The yield, as determined by evaporating the solvent and isolating crude Compound II, was in the neighborhood of 97 to 98%.

**C. Preparation of Compound III**

The solution of Compound II in toluene/ethyl acetate at 65°C–70°C was treated with 37% aqueous hydrochloric acid (160 g, 1.64 mol) over a period of 2 h. The mixture was then distilled at 70°C under reduced pressure (500–600 mm-Hg) until the residual ethyl acetate content was less than 5 mol % in toluene (as determined by 1H NMR analysis), and the water content was less than 1% (as determined by Karl Fischer analysis). When distillation was complete, the toluene volume was adjusted to 15% solids and ethanol (360 mL, denatured with 5 wt % Methanol) was added. The mixture was cooled to ambient temperature over 2 h, held at ambient for 1 h, then cooled to ~5°C to ~10°C for 1 h. The precipitated solid was isolated by filtration, washed with toluene and n-hexanes, and dried in vacuo at 80°C to give 247 g (73%) of Compound III. The purity of Compound III as determined by HPLC was 99.2 wt % (99.8 area %). Compound III was also characterized by 1H/13C NMR analysis.

**II. Process B: Methylen chloride Process**

**A. One Pot Process**

A solution of 2S,3S-CMA (44 g, 0.146 mol), isobutylamine (11 g, 0.150 mol) in 270 mL of methylene chloride was stirred with sodium hydrogen carbonate (33 g, 0.4 mol) in water (100 g) for 5 h. The mixture was cooled to ambient temperature over 2 h, held at ambient for 1 h, then cooled to ~5°C to ~10°C for 1 h. The precipitated solid was isolated by filtration, washed with toluene and n-hexanes, and dried in vacuo at 80°C to give 247 g (73%) of Compound III. The purity of Compound III as determined by HPLC was 99.2 wt % (99.8 area %). Compound III was also characterized by 1H/13C NMR analysis.

**B. Process Starting with Compound I**

A solution of triethylamine (17.7 g, 0.175 mol) and Compound I (49.0 g, 1.46 mol) in methylene chloride (270 mL) was heated to 30–35°C and a solution of n-sulfonyl chloride (35.4 g, 0.157 mol) in methylene chloride was added over 3 h. The solution is heated to 35°C and washed sequentially with water (65 mL), 5% sodium bicarbonate solution (60 mL) and water (80 mL). The solution was heated reflux and water removed azeotropically. When Karl Fischer analysis of the solution indicated that less than 0.1% of water remained, the solution was cooled to ambient. Hydrogen chloride gas was passed through the solution for 3 h until HPLC analysis indicated that the reaction was complete. The mixture was cooled to 0–5°C and filtered to give a white solid. The solid was washed with hexanes (65 mL) and dried in vacuo to give 59.5 g (89%) of compound III that was 99.7% pure by HPLC analysis.

It is understood that the examples and embodiments described herein are for illustrative purposes only and that...
various modifications or changes in light thereof will be suggested to persons skilled in the art and are to be included within the spirit and purview of this application and scope of the appended claims. All publications, patents, and patent applications cited herein are hereby incorporated by reference for all purposes.

What is claimed is:

1. A process for preparing a compound having the following general formula:

\[
\text{Formula III} \quad \text{III}
\]

said process comprising:

(a) combining a compound of Formula II with an aromatic solvent/alkyl acetate to form a reaction mixture and heating said reaction mixture, said compound of Formula II having the following general formula:

\[
\text{Formula II} \quad \text{II}
\]

(b) treating said reaction mixture with an acid having a \( pK_a \) of less than about 4 until the reaction is complete, thereby forming said compound of Formula III;

wherein:

- \( R^1 \) is an amino acid side chain or a functionalized amino acid side chain;
- \( R^2 \) is a protecting group;
- \( R^3 \) is a member selected from the group consisting of hydrogen, alkyl, cycloalkyl, aryl and \(-\text{NH}P\), wherein \( P \) is selected from the group consisting of \( \text{H, alkyl, cycloalkyl, aryl and a protecting group; and} \)
- \( X^- \) is the conjugate base of said acid.

2. The process in accordance with claim 1, wherein said compound of Formula II has the following general formula:

\[
\text{Formula III} \quad \text{III}
\]

3. The process in accordance with claim 2, wherein said compound of Formula III has the following general formula:

\[
\text{Formula III} \quad \text{III}
\]

4. The process in accordance with claim 1, further comprising recovering said compound of Formula III from said reaction mixture.

5. The process in accordance with claim 1, wherein said acid is a member selected from the group consisting of HCl, HBr, CF₃CO₂H, CF₃SO₃H, CH₃SO₃H, H₂SO₄, citric acid, tartaric acid, oxalic acid and p-toluene sulfonic acid.

6. The process in accordance with claim 5, wherein said acid is HCl.

7. The process in accordance with claim 5, wherein said acid is CH₃SO₃H.

8. The process in accordance with claim 6, wherein said hydrochloric acid is about 37% aqueous hydrochloric acid.

9. The process in accordance with claim 5, wherein said hydrochloric acid is gaseous hydrochloric acid.

10. The process in accordance with claim 1, wherein said alkyl acetate is a member selected from the group consisting of methyl acetate, ethyl acetate, isopropyl acetate and isobutyl acetate.

11. The process in accordance with claim 1, wherein said aromatic solvent is a member selected from the group consisting of toluene, benzene and xylene.

12. The process in accordance with claim 1, wherein said aromatic solvent/alkyl acetate is toluene/ethyl acetate.

13. The process in accordance with claim 1, wherein said reaction mixture is heated to a temperature ranging from about 50° C. to about 100° C.

14. The process in accordance with claim 1, wherein said reaction mixture is heated to a temperature ranging from about 45° C. to about 80° C.

15. The process in accordance with claim 1, wherein said reaction mixture is treated with said acid for a time period of at least about 0.5 hours.

16. A process for preparing a compound having the following general formula:

\[
\text{Formula III} \quad \text{III}
\]

said process comprising:

(a) combining a compound of Formula II with a halogenated solvent to form a reaction mixture and heating said reaction mixture to a temperature ranging from about 10° C. to about 50° C., said compound of Formula II having the following general formula:
19. The process in accordance with claim 16, further comprising recovering said compound of Formula III from said reaction mixture.

20. The process in accordance with claim 16, wherein said halogenated solvent is a member selected from the group consisting of methylene chloride, chloroform, trifluorotoluene (oxsol), parachlorotrifluorotoluene and trichloroethylene.

21. The process in accordance with claim 16, wherein said halogenated solvent is methylene chloride.

22. The process in accordance with claim 16, wherein said acid is a member selected from the group consisting of HCl, HBr, CF₃CO₂H, CF₃SO₃H, CH₃SO₃H, H₂SO₄, citric acid, tartaric acid, oxalic acid and p-toluene sulfonic acid.

23. The process in accordance with claim 22, wherein said acid is HCl.

24. The process in accordance with claim 22, wherein said acid is CH₃SO₃H.

25. The process in accordance with claim 23, wherein said hydrochloric acid is gaseous hydrochloric acid.

26. The process in accordance with claim 16, wherein said reaction mixture is treated with said acid for a time period of at least about 0.5 hours.

27. The process in accordance with claim 16, wherein said reaction mixture is heated to a temperature ranging from about 30° C. to about 35° C.
