A $p$-Adic Cohomological Method for the Weierstrass Family and Its Zeta Invariants

GORO KATO
Dedicated to my parents.

ABSTRACT. After a survey of the Weierstrass family and cohomology, we compute the lifted homology of the Weierstrass family with compact supports so that explicit formulae for the zeta function of each fibre of the Weierstrass family may be obtained. The (co-)homology theory that we use is found in [L1], [L2] and [L3]. Therefore, this article can be regarded as an application of Lubkin's $p$-adic theory of cohomologies to an algebraic family called the Weierstrass scheme over the ring $(\mathbb{Z}/p\mathbb{Z})[g_2,g_3]$. The cohomological background for the computation will be rather carefully exploited.

1. Introduction

One of the most fundamental motivations in algebraic geometry is to study the common zero points of a finite number of polynomials in several variables, and one of the main goals in number theoretic algebraic geometry is to count the number of common zero points of the set of polynomials.

The congruence zeta function associated with the polynomials provides the number of zeros. That is, let $k = \mathbb{F}_q$ be a finite field of $q = p^a$ elements, and let $V$ be an algebraic variety over $k$ and a complete scheme embedded in the projective space $\mathbb{P}^N(\Omega)$ over the universal domain $\Omega$.

The final version of this paper will appear in [K].

Partially supported by CARE Grant 5917.
For each natural number $m = 1, 2, \ldots$, let $k_m \subset \Omega$ be the unique extension of degree $m$ over $k$, i.e. $k_m = \mathbb{F}_{q^m}$. The finite set $N_m$ denotes the number of points on $V$ whose coordinates are in $k_m$, i.e. $k_m$-rational points on $V$. That is,

$$N_m = |V \cap \mathbb{P}^N(k_m)|.$$ 

First consider the infinite series in $u$:

$$N_1 + N_2u + N_3u^2 + \ldots,$$

whose integral is given by

$$N_1u + \frac{N_2}{2}u^2 + \frac{N_3}{3}u^3 + \ldots.$$ 

The congruence zeta function of $V$ is defined by

$$Z_V(u) = \exp\left(N_1u + \frac{N_2}{2}u^2 + \frac{N_3}{3}u^3 + \ldots \right).$$

Notice that the first few terms look like

$$Z_V(u) = 1 + N_1u +$$

$$\left(\frac{N_2}{2} + \frac{1}{2}N_1^2\right)u^2 + \left(\frac{N_3}{3} + \frac{N_1N_2}{2} + \frac{N_1^3}{3!}\right)u^3 + \ldots.$$ 

Therefore, it is sufficient to know the explicit form of the zeta function to know numbers of zeros, $N_1, N_2, \ldots$ in $\mathbb{P}^N(k_1), \mathbb{P}^N(k_2), \ldots$ respectively. An invariant called a $p$-adic cohomology group of $V$ will be the device for us to compute the zeta function of $V$ in what follows.
We are mainly concerned with the Weierstrass family and its zeta function (zeta matrix). This is one of few cases where exact computation is possible, and applications to factoring integers via elliptic curves may be possible. See [Le].

The Weierstrass family \( \mathcal{W}_R \) corresponding to any ring \( R \) with \( 1_R \) is obtained by a normalization by linear changes of coordinates of “the square root of a general cubic family” \( Y^2 = ax^3 + bx^2 + cx + d, \ a \neq 0 \). Geometrically speaking, the Weierstrass family \( \mathcal{W}_R \) is the pull-back of the square root of the general cubic family

\[
\text{Proj}([a, a^{-1}, b, c, d, X, Y, Z] / (\text{homogeneous ideal generated by } -Y^2Z + ax^3 + bx^2Z + CXZ^2 + dZ^3))
\]

under the closed immersion

\[
\text{Spec } (R[g_2, g_3]) \subseteq \text{Spec } (R(a, a^{-1}, b, c, d)).
\]

Here, the closed immersion is defined by the ideal generated by \( \{a - 4, b, c + g_2, d + g_3 \} \) and such that 2 is invertible in \( R \). Explicitly,

\[
\mathcal{W}_R = \text{Proj}(R[g_2, g_3, X, Y, Z] / (\text{homogeneous ideal generated by } -Y^2Z + 4X^3 - g_2XZ^2 - g_3Z^3)),
\]

where each of \( X, Y \) and \( Z \) has degree +1 and all the elements of \( R[g_2, g_3] \) have degree zero in the \( R[g_2, g_3] \)-algebra \( R[g_2, g_3, X, Y, Z] \). On the other hand, the above linear changes provide a map over \( \text{spec } R \).
Spec \((R[g_2, g_3]) \leftarrow \text{Spec } (R[a, a^{-1}, b, c, d])\)
such that the pull-back of \(\mathcal{W}_R\) under this map is canonically isomorphic to the general cubic family, assuming \(6\) is invertible in \(R\).

By applying the Jacobian criterion to the corresponding affine algebraic Weierstrass family over \(\text{Spec } (R[g_2, g_3])\), we find that the set of points of the base \(\text{Spec } (R[g_2, g_3])\) over which the fibre is singular is the set of all the points on the hypersurface
\[
\Delta = g_2^3 - 27g_3^2 = 0.
\]

Note that for a point \(p \in \text{Spec } (R[g_2, g_3])\) on the base of \(\mathcal{W}_R\) the fibre of \(\mathcal{W}_R\) over \(p\) is singular if and only if \(\Delta = g_2^3 - 27g_3^2\) vanishes at \(p\), i.e. \(\Delta\) goes into zero in \(K(p)\), the residue class field at \(p\). At such a point \(p\), observe that all the singular points lie on the affine open \(\text{Spec } (K(p)[X, Y]/(y^2 - 4X^3 + g_2X + g_3))\). There is one and only one singular point on this affine open, i.e. \((0,0)\) or
\[
\left(-\frac{3}{2} \frac{g_3^{(0)}}{g_2^{(0)}}, 0\right)
\]
for the images \(g_2^{(0)}, g_3^{(0)}\) of \(g_2, g_3\) in \(K(p)\): \(g_2^{(0)} = 0\), or \(g_3^{(0)} \neq 0\) (hence \(g_2^{(0)} \neq 0\)), respectively. Notice that the singular point on the singular fibre is a rational point over \(K(p)\).

Furthermore, if \(\Delta = 0\) but \(g_2^{(0)} \neq 0\) (hence \(g_3^{(0)} \neq 0\)), then exactly two of
\[
\Delta = 0, \qquad \Delta = 0,
\]
equal, i.e.

Let the field \(K\) isomorphic \(H^c_{\text{h}}(X, \mathbb{C})\) of the cohomology group \(H^c_{\text{h}}(X, \mathbb{C})\) let \(X\) to the topology of the class field to the cohomology group to the cohomology group.

The provided text seems to be a continuation of a mathematical discussion involving algebraic geometry and number theory, specifically focusing on the properties of certain cubic curves and their singularities. The notation and formulas suggest a deep dive into the theory of algebraic curves and their associated Jacobian varieties.
Let $X$ be a complex algebraic variety which is embeddable over the field of complex numbers $\mathbb{C}$. Then there exists a canonical isomorphism between the homology of $X$ with compact supports $H^*(X, \mathbb{C})$ (see [1] for its definition) and the usual singular homology $H^*(X_{\text{top}})$ of the classical topological space $X_{\text{top}}$ with compact supports. That is, let $X_{\text{top}}$ be the closed points of $X$ with the classical Hausdorff topology. Then by the definition of $H^*(X, \mathbb{C})$, one shows $H^*(X, \mathbb{C}) = H^*(X_{\text{top}}, \mathbb{C})$, the usual singular homology with compact supports. The proof is given essentially by definition of $H^*(X, \mathbb{C})$. Since $X$ is simple over $\mathbb{C}$, so that $X$ may be closed in $Y$. Then $H^*(X, \mathbb{C})$ is canonically $H^*(Y, X, \mathbb{C})^* = H^*(Y_{\text{top}}, X_{\text{top}}, \mathbb{C})^*$, the oriented singular cohomology. By Lefschetz duality being applied to the oriented $2N$-dimensional topological manifold $Y_{\text{top}}$ and the classical singular cohomology, we have $H^*(Y_{\text{top}}, X_{\text{top}}, \mathbb{C})^*$ canonic ally $H^*(Y_{\text{top}}, X_{\text{top}}, \mathbb{C})^*$.
\[ \check{H}_c^h(X_{\text{top}}, \mathbb{C}) \]. Here \( \check{H}_c^h(X_{\text{top}}, \mathbb{C}) \) denotes the classical Čech cohomology. Since \( X \) is an algebraic variety, we have \( \check{H}_c^h(X_{\text{top}}, \mathbb{C}) = H_c^h(X_{\text{top}}, \mathbb{C}) \). All the groups are finitely generated over \( \mathbb{C} \). Hence, taking the duality, we have

\[ H^{2N-h}(Y_{\text{top}}, Y_{\text{top}} - X_{\text{top}}, \mathbb{C}) \approx H_c^h(X_{\text{top}}, \mathbb{C}), \]

completing the proof.

Particularly, if \( X \) is an embeddable complete complex algebraic variety, then \( H_c^h(X, \mathbb{C}) = H^h(X_{\text{top}}, \mathbb{C}) \).

On a compact topological space, singular homology with compact supports is the same as ordinary singular homology. In particular for a fibre \( X \) of the Weierstrass family over a point \( \mathfrak{p} \) in the base where \( \mathbb{K}(\mathfrak{p}) = \mathbb{C} \), we have the following:

\[ H_0^c(X, \mathbb{C}) = \mathbb{C} \]

\[ H_1^c(X, \mathbb{C}) = \begin{cases} \mathbb{C} \oplus \mathbb{C} & \text{for an elliptic curve } X \\ \mathbb{C} & \text{for a projective line with an ordinary double point} \\ 0 & \text{for a projective line with a cusp} \end{cases} \]

\[ H_2^c(X, \mathbb{C}) = \mathbb{C} \]

and \( H_h^c(X, \mathbb{C}) = 0 \) for \( h \neq 0, 1, 2 \).
Another general principle for varieties over characteristic zero fields is the following theorem.

**THEOREM.** Let $K$ be a field of characteristic zero, let $L$ be an extension field of $K$. Let $X$ be an algebraic variety over $K$ which is embeddable over $K$. Then $X \times L$ is an algebraic variety over $L$, and we have canonically

$$H^c_h(X, K) \otimes L = H^c_h(X \times L, L)$$

as vector spaces over $L$.

The proof of this theorem goes as follows. Let $Y$ be simple over $K$ containing $X$ as a closed subvariety. By the facts $Y \times L$ is affine over $Y$ and the direct image of $\Omega^*_L(Y \times L)$ is $(\Omega^*_K(Y)) \otimes L$, we have

$$H^h(Y, Y - X, \Omega^*_K) \otimes L = H^h(Y \times L, Y \times L - X \times L, \Omega^*_L).$$

**NOTE.** If we have such a hypothesis as: $K$ and $L$ are rings containing $\mathbb{Q}$ and there is a ring homomorphism from $K$ to $L$, the conclusion of the above theorem becomes a right half plane spectral sequence

$$\text{Tor}_p(H^c_q(X, K), L) \Rightarrow H^c_n(X, L).$$
See the forthcoming [K]. A generalization of the spectral sequence to the non-constant characteristics is difficult, since the dagger completion is involved.

Namely, one can compute the homology with compact supports of any embeddable variety $X$ over a field $K$ of characteristic zero by the following Lefschetz Principle:

For a field $K$ embeddable in the field of complex numbers $\mathbb{C}$, by the theorem above,

$$(LP) \quad H^c_h(X, K) \otimes \mathbb{C} = H^c_h(X \times \mathbb{C}, \mathbb{C})$$

holds. The right-hand side is the classical complex homology with compact supports of the complex algebraic variety $X \times \mathbb{C}$. If $K$ is an arbitrary field of characteristic zero, $H^c_h(X, K)$ can still be computed by an embeddable algebraic variety $X_0$ over a finitely generated field $K_0$ over $\mathbb{Q}$ with $X_0 \times K_0 = X$. That is, $H^c_h(X, K) = H^c_h(X_0, K_0) \otimes K$, $H^c_h(X_0, K_0)$ can be handled by (LP) above.

We will apply what we have mentioned to the fibres of the Weierstrass family.

**PROPOSITION.** Let $X$ be a fibre of the Weierstrass family $\mathbb{W}_R$, corresponding to any commutative ring $R$ with identity, over a point $p \in \text{Spec } R$. Then we have

\[
\begin{align*}
H^c_0(X, K) &= k \\
H^c_1(X, K) &= k \\
H^c_2(X, K) &= 0
\end{align*}
\]

Next let $k = \text{ring and be a con}$ as its res followin

**PROP** homolog
\( \varphi \in \text{Spec}(R[g_2, g_3]) \) such that \( k = \mathbb{K}(\varphi) \) is of characteristic zero.

Then we have:

\[
H^0_c(X, k) = k
\]

\[
H^1_c(X, k) =
\begin{cases}
  k \oplus k, & \text{if } X \text{ is non-singular, i.e., } X \text{ is an elliptic curve} \\
  k, & \text{if } X \text{ is a projective line with an ordinary double point} \\
  0, & \text{if } X \text{ is a projective line with a cusp}
\end{cases}
\]

\[
H^2_c(X, k) = k, \quad \text{and}
\]

\[
H^h_c(X, k) = 0 \text{ for } h = 3, 4, \ldots.
\]

Next we will consider the non-zero characteristic case. Let \( R \) be a ring and let \( X \) be a fibre of \( W_R \) over some \( \varphi \in \text{Spec}(R[g_2, g_3]) \).

Let \( k = \mathbb{K}(\varphi) \). Suppose the characteristic \( p \) of \( k \) is not zero. Let \( \mathcal{O} \) be a complete discrete valuation ring with mixed characteristics with \( k \) as its residue class field and \( K \) as the quotient field of \( \mathcal{O} \). We have the following facts.

**Proposition.** If \( X \) is non-singular, then the lifted \( K \)-adic homology with compact supports behaves as follows:

\[
H^c_h(X, K) =
\begin{cases}
  K & \text{for } h = 0 \text{ or } 2 \\
  K \oplus K & \text{for } h = 1 \\
  0 & \text{for } h \neq 0, 1, 2
\end{cases}
\]
PROOF. If $X$ is liftable over $\mathcal{O}$ by a simple and proper lifting over $K$, then $X_K$ is an elliptic curve. Then $H^c_h(X, K) = H^{2N-h}(X, K)$ by taking $Y = X$ in the definition. Then, by \cite{L1}, $H^{2N-h}(X, K)$ is isomorphic to the hypercohomology $H^{2N-h}_c(X_K, K)$. We have $H^{2N-h}_c(X_K, K) = H^c_h(X_K, K)$, where $H^c_h(X_K, K)$ is computed in the previous proposition for $h = 0, 1, 2, \ldots$.

If $X$ is a singular fibre, then one can prove $H^c_0(X, K) = K$, $H^c_2(X, K) = K$ and $H^c_h(X, K) = 0$ for $h = 3, 4, \ldots$. In the following section, we will prove the following by direct computation:

$$H^c_1(X, K) =$$

\[
\begin{cases} 
K, & \text{if } X \text{ is a projective line with an ordinary double point} \\
0, & \text{if } X \text{ is a projective line with a cusp.}
\end{cases}
\]

**NOTE** Each fibre $X$ of the Weierstrass scheme $\mathcal{W}_R$ over $\mathfrak{p} \in \text{Spec } (R[\beta_2, \beta_3])$ has a rational and simple point, called the point at infinity with homogeneous coordinates $(0,1,0)$. We denote the affine curve obtained from $X - (0,1,0)$ by $U$. The long exact sequence of the homology with compact supports is induced as:

$$\cdots \rightarrow H^c_{h-2n}((0,1,0), K) \rightarrow H^c_h((0,1,0), K) \rightarrow H^c_h(X, K) \rightarrow H^c_h(U, K) \rightarrow \cdots,$$
where \( n = \dim X = 1 \) in our case. The first homology group is trivial unless \( h = 2 \). Therefore, it suffices to compute \( H^1_0(U, K) \). Note also that \( U \) is closed in \( \mathbb{A}^2(k) = \text{Spec} (k[X, Y]) \), whose lifting is given by \( \mathbb{A}^2(\mathcal{O}) = \text{Spec} (\mathcal{O}[X, Y]) \). Then \( H^c_0(U, K) = H^{4-h}(\mathbb{A}^2(k), \mathbb{A}^2(k) - U, \Omega^*_\mathcal{O}((\mathbb{A}^2(\mathcal{O}))^\dagger \otimes K), h \in \mathbb{Z} \). Since \( \mathbb{A}^2(k) \) and \( \mathbb{A}^2(k) - U \) are both affine open sets, the covering \( \{ \mathbb{A}^2(k), \mathbb{A}^2(k) - U \} \) may be used to compute the homology group.

### 3. The Universal Coefficient Spectral Sequence

Let \( A \) be an \( \mathcal{O} \)-algebra with an endomorphism \( F \) on \( A \) such that \( F \) induces the \( p \)-th power endomorphism of \( A = A / pA \), where \( p \) is the characteristic of \( k = \mathcal{K}(\mathcal{O}) \). Then there exists a unique ring homomorphism

\[
\Delta \to W(A^{p^{\infty}}),
\]

where \( W(A) \) is the Witt vector of \( A = A / pA \), such that the above ring homomorphism is compatible with the endomorphism \( F \) of \( A \), inducing the identity of \( A \). The construction of the ring homomorphism \( \Delta \to W(A) \) is as follows: let \( \Delta^{F^{\infty}} \) be the direct limit of the sequence

\[
\Delta \to \Delta \to \Delta \to \Delta \to \cdots
\]
Then, $\Delta^{F_{\infty}}$ obeys the universal characterization of the Witt vector $W(A)$ of $A$. Next let $\mathfrak{p}$ be a prime ideal of $A$. Then we have a natural map from $\Delta$ into $W(\mathbb{K}(\mathfrak{p}))^{p_{\infty}}$, which is compatible with $F$.

For example, if $\mathbb{K}(\mathfrak{p})$ is perfect, there is induced a unique ring homomorphism from $\Delta$ into $W(\mathbb{K}(\mathfrak{p}))$ of $\mathbb{K}(\mathfrak{p})$. If $\mathbb{K}(\mathfrak{p})$ is a finite field, then there is a natural homomorphism

$$\Delta \to W(\mathbb{K}(\mathfrak{p})),$$

where $W(\mathbb{K}(\mathfrak{p}))$ is the unique Witt vector of $\mathbb{K}(\mathfrak{p})$ that is the mixed characteristic complete discrete valuation ring with its residue class field $\mathbb{K}(\mathfrak{p})$. In the case of the Weierstrass family, we let $\Delta = \mathbb{Z}_p[g_2, g_3]$.

Then for any given closed point $\mathfrak{p} \in \text{Spec} (A)$, the residue class field $\mathbb{K}(\mathfrak{p})$ is finite. Then the images $g_2^{(0)}$ and $g_3^{(0)}$ of $g_2$ and $g_3$ in $\mathbb{K}(\mathfrak{p})$ generate $\mathbb{K}(\mathfrak{p})$ over the prime field, i.e. $\mathbb{K}(\mathfrak{p}) = (\mathbb{Z}/p\mathbb{Z})[g_2^{(0)}, g_3^{(0)}]$. The Witt vector $W(\mathbb{K}(\mathfrak{p}))$ of $\mathbb{K}(\mathfrak{p})$ can be described as follows: each of $g_2^{(0)}$ and $g_3^{(0)}$ is either a root of unity of order prime to $p$, or else zero. Choose an element $\mathfrak{p} \in \mathbb{K}(\mathfrak{p})$ which is a multiplicative generator of the multiplicative cyclic group $\mathbb{K}(\mathfrak{p}) - \{0\}$. Then each $\mathfrak{p}$ or else $\mathbb{Z}_p$ as a prime index generate similarly. Let $W(\mathbb{K}(\mathfrak{p}))$ be a ring and

$$(\mathbb{K}(\mathfrak{p}))_{\text{red}} \subset W(\mathbb{K}(\mathfrak{p}))$$

Let $W(\mathbb{K}(\mathfrak{p}))$ be a ring and

over $S$.
Then each element of \( \mathbb{K}(p) \), e.g. \( g_2^{(0)} \) and \( g_3^{(0)} \), is either a power of \( p \) or else zero. Let \( a \) be the multiplicative order of \( p \). Then embed \( \hat{\mathbb{Z}}_p \) as a subring of \( \mathbb{C} \), and let \( p' \) be any fixed root of unity in \( \mathbb{C} \) of order exactly \( a \). Then, \( W(\mathbb{K}(p)) = \hat{\mathbb{Z}}_p [p'] \), i.e., the subring of \( \mathbb{C} \) generated by \( \hat{\mathbb{Z}}_p \) and \( p' \). Let \( (g_2^{(0)})' = (p')^i \), where \( g_2^{(0)} = p^i \) and similarly for \( g_3^{(0)} \). If \( g_2^{(0)} = 0 \), then define \( (g_2^{(0)})' = 0 \). They are Teichmüller representatives of \( g_2^{(0)} \) and \( g_3^{(0)} \) in \( W(\mathbb{K}(p)) \).

Let \( A \) be an \( \mathcal{O} \)-algebra, and let \( F \) be a ring endomorphism of \( A \) which induces the \( p \)-th power endomorphism of \( A / pA \). Then, for any prime ideal \( \mathfrak{p} \in \text{Spec} (A \otimes k)_{\text{red}} \), we have shown in the above how one obtains a natural homomorphism from \( A \) to \( W(\mathbb{K}(p)) \). For example, for \( A = \hat{\mathbb{Z}}_p [g_2, g_3] \), if \( \mathfrak{p} \) is a maximal ideal of \( A = (A / pA)_{\text{red}} = (A \otimes k)_{\text{red}} \) so that \( \mathbb{K}(p) = (\hat{\mathbb{Z}} / p\hat{\mathbb{Z}})[g_2^{(0)}, g_3^{(0)}] \), then \( W(\mathbb{K}(p)) = \hat{\mathbb{Z}}_p [(g_2^{(0)})', (g_3^{(0)})'] \). In this case, the natural map \( A \to W(\mathbb{K}(p)) \) is given by \( g_2 \mapsto (g_2^{(0)})' \) and \( g_3 \mapsto (g_3^{(0)})' \).

Let \( B = W(\mathbb{K}(p))^{\mathcal{O}} \). Then \( B \) is a complete discrete valuation ring and \( B \otimes \mathbb{Q} \) is a field of characteristic zero. If \( X \) is a scheme over \( \text{Spec} (A) \) that is embeddable over \( A \), then the fibre \( X_{\mathfrak{p}} \) over
$K(\mathfrak{p})$ is an algebraic variety over the field $K(\mathfrak{p})$. Let $Y_\mathfrak{p} = X_\mathfrak{p} \times_{K(\mathfrak{p})} K(\mathfrak{p})^{p\infty}$. Then the zeta matrices have coefficients in the quotient field $K_\mathfrak{p} = \mathcal{B} \otimes Q$ of the complete discrete valuation ring $\mathcal{B} = W(K(\mathfrak{p})^{p\infty})$. The universal coefficient spectral sequence is:

$$E^{2}_{p,q} = \text{Tor}_{p} Z \left( H^{c}_{q}(X, A^{\dagger} \otimes Q), K_{\mathfrak{p}} \right)$$

with the abutment $H^{c}_{n}(Y_\mathfrak{p}, K_{\mathfrak{p}})$. Principally speaking, this universal spectral sequence shows how the lifted $p$-adic homology of the scheme $X$ over Spec $(A)$ with compact supports determines the lifted $p$-adic homology of all the fibres $Y_\mathfrak{p}$ in this algebraic family. Furthermore, the zeta endomorphisms of $H^{c}_{*}(X, A^{\dagger} \otimes Q)$ compute the zeta endomorphisms of $H^{c}_{*}(Y_\mathfrak{p}, K_{\mathfrak{p}})$ of each fibre $Y_\mathfrak{p}$.

Suppose that $K(\mathfrak{p})$ is a finite field. If the term $E^{2}_{p,q}$ of the above universal coefficient spectral sequence is finite dimensional over the quotient field $K_{\mathfrak{p}}$ of the complete discrete valuation ring $W(K(\mathfrak{p}))$ for all the $p$ and $q$, we can compute the zeta function of each fibre.
quotient field

This universal

of the scheme

lifted p-adic

Furthermore, 

date the zeta

of the above

onal over the

ig W(K(p))
of each fibre

\[ Y_p = X_p \times_{K(p)} \] 

as follows. Let \( P_{p,q} \) be the reverse characteristic polynomial of the endomorphism of the \( E^2_{p,q} \)-term, which is induced by \( p^r \)-th power map, \( p^r = \text{card}(K(p)) \). Then, the zeta function of the fibre \( X_p \) is provided by the formula

\[
Z_{X_p}(T) = \frac{\prod_{p+q=\text{odd}} P_{p,q}(T) \prod_{p+q=\text{even}} P_{p,q}(T)}{\prod_{p+q=\text{odd}} P_{p,q}(T) \prod_{p+q=\text{even}} P_{p,q}(T)}
\]

where we assume that \( E^2_{p,q} = 0 \) for all but finitely many pairs of \( p \) and \( q \). When the lifted p-adic homology with compact supports is a free module, the zeta endomorphism is said to be the zeta matrix.

4. Zeta Endomorphisms and Zeta Matrices

We will compute the zeta endomorphism of the first homology group with compact supports of the finite points of the Weierstrass family \( H^c_1(U, A^+ \otimes \mathbb{Q}) \). That is:

\[
U = W_{Z/pZ} \cap \mathbb{A}^2(\text{Spec}((Z/pZ)[g_2, g_3])).
\]

Note that \( H^c_1(U, A^+ \otimes \mathbb{Q}) \cong H^c_1(W_{Z/pZ}, A^+ \otimes \mathbb{Q}) \) as seen, e.g., in [K_2]. Let \( K \) be the quotient field of \( A = \hat{Z}_p [g_2, g_3] \), and let \( K^+ \) be
the quotient field of \( \Delta^+ = \mathbb{Z}_p [g_2, g_3]^+ \). Even though \( H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \) is not finitely generated over \( \Delta^+ \otimes \mathbb{Q} \), \( H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \otimes \mathbb{K} \) is a vector space of dimension two over \( \mathbb{K} \). From the universal spectral sequence corresponding to any non-zero-diver \( t \in \Delta \), we have the long exact sequence:

\[
\cdots \to H^c_h(U, \Delta^+ \otimes \mathbb{Q}) \xrightarrow{t^*} H^c_h(U, \Delta^+ \otimes \mathbb{Q}) \to \cdots.
\]

One can extract the short exact sequence

\[
0 \to H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \xrightarrow{t^*} H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \to \cdots
\]

Hence, \( H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \) is torsion free, i.e., we have

\[
H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \hookrightarrow H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \otimes \mathbb{K}.
\]

The zeta matrix of the free module of rank two

\[
H^c_1(U, \Delta^+ \otimes \mathbb{Q}) \otimes \mathbb{K} \otimes (A^+_{\Delta} \otimes \mathbb{Q})
\]
is computed in [K-L]. This free module is isomorphic to the $A_\Delta^+ \otimes \mathbb{Q}$

$Q$-adic cohomology of the open subfamily $U_\Delta$ of non-singular fibres,
denoted as $H^1(U_\Delta, A_\Delta^+ \otimes \mathbb{Q})$. The above isomorphism may be given
between generators by

$$C^{-1} dX \wedge dY \rightarrow Y dX$$

$$X C^{-1} dX \wedge dY \rightarrow XY dX,$$

where $C = Y^2 - 4X^3 + g_2X + g_3$. (See what will follow.)

The zeta matrix $W^1 \in \text{Mat}_{2 \times 2}(A_\Delta^+ \otimes \mathbb{Q})$ on the free $A_\Delta^+ \otimes \mathbb{Q}$
module $H^1(U_\Delta, A_\Delta^+ \otimes \mathbb{Q})$ is given as follows: let $F : \Delta \rightarrow \Delta$ be an
endomorphism of $\hat{\mathbb{Z}}_p$-algebra, inducing $p$-th power map on $A$,
defined by

$$F(g_2) = g_2^p \text{ and } F(g_3) = g_3^p.$$

Let $f : U_\Delta \rightarrow U_\Delta$ be the $p$-th power endomorphism of the scheme $U_\Delta$
over $A_\Delta$. Then define

$$H^1(F, f)(Y dX) = p X^{p-1} \sqrt{4X^3p - g_2^pX^p - g_3^p} \ dX$$
and

\[ H^1(F, f)(XY \; dX) = pX^{2p-1} \sqrt{4X^3p - g_2^pX^p - g_3^p} \; dX, \]

where

\[
\sqrt{4X^3p - g_2^pX^p - g_3^p} = \sqrt{(4X^3 - g_2X - g_3)^p - pT} = \sqrt{Y^{2p} - pT} = y^p \left( \sum_{i \geq 0} \binom{1}{i} \left( \frac{-pT}{(4X^3 - g_2X - g_3)^p} \right)^i \right),
\]

here \( pT = (4X^3 - g_2X - g_3)^p - 4X^{3p} + g_2^pX^p + g_3^p \). See [K-L] for necessary recursive formulae.

Therefore, the zeta endomorphism of \( H^c_1(U, \Delta^\dagger \otimes \mathbb{Q}) \) is induced from this zeta matrix by the above restriction

\[ H^c_1(U, \Delta^\dagger \otimes \mathbb{Q}) \rightarrow H^c_1(U, \Delta^\dagger \otimes \mathbb{Q}) \otimes K. \]

The actual construction is as follows: by the definition of the lifted \( p \)-adic homology with compact supports of the Weierstrass family over \( A = (\mathbb{Z}/p\mathbb{Z})[g_2, g_3], \)
\[ H_1^c(U, \Delta^+ \otimes \mathbb{Q}) = H^3(\mathbb{A}^2(\text{Spec}((\mathbb{Z}/p\mathbb{Z})[g_2, g_3])), \) \\
\mathbb{A}^2(\text{Spec}((\mathbb{Z}/p\mathbb{Z})[g_2, g_3])) - U, \) \\
\Omega^*_D(\mathbb{A}^2(\text{Spec}(\mathbb{Z}_p[g_2, g_3])))^+ \otimes \mathbb{Q}). \]

By the lemma in [K1] on spectral sequences, one shows this third relative hypercohomology is isomorphic to

\[ \text{Coker } (\Omega^1_D(\mathbb{A}[X, Y, C^{-1}])^+ \otimes \mathbb{Q}) \xrightarrow{d_1^{1,0}} \Omega^2_D(\mathbb{A}[X, Y, C^{-1}])^+ \otimes \mathbb{Q}). \]

We obtain the recursive cohomologous relations among the generators of \( H_1^c(U, \Delta^+ \otimes \mathbb{Q}) \) as

\[
\begin{align*}
2(i-1)\Delta C^{-i} dX \wedge dY & \sim (6i-13)g_2XC^{-i}dX \wedge dY -(6i-11)9g_3C^{-i}dX \\
& \wedge dY, \text{ and} \\
4(i-1)\Delta XC^{-i} dX \wedge dY & \sim (6i-11)g_2^2C^{-i}dX \\
& \wedge dY -(6i-13)18g_3XC^{-i}dX \wedge dY.
\end{align*}
\]

Therefore, we let

\[ H_1^c(F, f)(C^{-1} dX \wedge dY) = \frac{p^2X^{p-1}Y^{p-1}}{C^p - pT} \ dX \wedge dY \]

and

\[ H_1^c(F, f)(XC^{-1} dX \wedge dY) = \frac{p^2X^{2p-1}Y^{p-1}}{C^p - pT} \ dX \wedge dY, \]
where \( \frac{1}{C^p - pT} = C^p(1 + pTC^p + p^2T^2C^{-2p} + p^3T^3C^{-3p} + \ldots) \). See [K_2] for necessary recursive formulae. Notice that the above recursive cohomologous relations compute the lifted homology groups of various singular fibres, e.g., the fiber over \( \mathfrak{p} = (g_2, g_3) \) has the trivial homology group. See page 10.

**NOTES**

1. The universal spectral sequences are treated in the book [L_4], Chapter 5. As for zeta invariants, see [L_1], [L_2], [K-L] and [K_2].

2. A similar computation of \( p \)-th power map of Fermat curves may be given as follows: let \( U \) be the affine Fermat curve given by \( X^l + Y^l = 1 \) over \( \mathbb{Z}/p\mathbb{Z} \). Then the associated \( \hat{\mathbb{Z}}_p \otimes \mathbb{Q} \)-adic cohomology \( H^1(U, \hat{\mathbb{Z}}_p \otimes \mathbb{Q}) \) is generated by \( (l - 1) \times (l - 2) \) elements \( \{X^\alpha Y^{\beta-l+1}dX \} \), where \( \alpha = 0, 1, \ldots, l - 3 \) and \( \beta = l - 1, l, \ldots, 2l - 3 \). There is a cohomologous relation:

\[
x^{i+1-2}Y^{\beta-l+1}dX \sim x^{i+2l-2}Y^{\beta-l+1}dX
\]

for \( i = 0, 1, \ldots, l - 1 \). Then the \( (l - 1) \times (l - 2) \) square matrix \( H^1(f, \hat{\mathbb{Q}}_p) \) on \( H^1(U, \hat{\mathbb{Q}}_p) \) is defined as

\[
H^1(f, \hat{\mathbb{Q}}_p)(x^{\alpha}Y^{\beta-l+1}dX)
\]
where \( u = (1 - X^l)^p, \ P = (1 - X^l)^p - (1 - X^l) \).

See I. V. Volovich, p-adic string, Class. Quantum Grav. 4 (1987), 83, for a connection to a p-adic string theory. See also [Ko].
