What Do Animals Care About?

Lilly-Marlene Russow
Purdue University

Editors' note: This paper by Professor Russow, the response by Professor Stephens, and the reply by Russow were presented at the Pacific Division meetings of the Society for the Study of Ethics and Animals, held in San Francisco, California, March, 1995.

I am going to argue for a thesis that almost nobody in this audience would dispute: animals have things they care about, and the fact that animals care about them has moral significance. However, the lack of disagreement (in this forum, at least) should not disguise the fact that more work needs to be done, both to answer a recent spate of attempts to deny the thesis and to clarify exactly what "caring about" means, covers, and entails for our moral theories.

It might be more natural to talk about animals' interests, rather than what they care about. Unfortunately, this term has been interpreted in so many different ways that its use invites confusion. On one end of the spectrum, Tom Regan wants to allow for both preference and welfare interests, where the latter can involve things about which the subject knows or understands nothing.1 On the other end, R.G. Frey associates "interests" with terms such as "wants" and "desires," and further argues that these states require a language.2 Rather than try to dictate which of these interpretations more nearly reflects ordinary English usage (a misguided project at best), I have chosen to use a term which I hope (a) has less "baggage," at least in the debate about animals, (b) will allow me to specify what "caring about" means, and why it is important, and (c) in both ordinary usage and the broader philosophical tradition captures a distinction that is worth preserving.

R.G. Frey is perhaps the most familiar defender of the position that animals cannot have desires. Although he does not use terms like "care about," his conclusion also entails that animals are incapable of caring about things in the sense to be defined below. His argument can be summarized as follows:

P-1. In order for S to desire O, S must have some beliefs about O.
P-2. Beliefs require the ability to entertain and accept certain statements as true, and hence the ability to draw a distinction between true and false statements.
P-3. The ability to draw a distinction between true and false statements requires the use of language, and some understanding of how language represents states of affairs.
P-4. Animals lack the requisite linguistic abilities.
C. Therefore, animals lack beliefs, desires, and interests.3

Although this argument is most closely associated with Frey, it has been echoed by Michael Leahy.4 Both agree, for example, that Regan's broader use of...
"interest" cannot be sufficient to establish moral relevance, since Regan's concept of interests would, according to them, entails that tractors as well as can have "interests" in that sense.

Many animal scientists also reject talk of animals' interests or desires or caring, usually preferring terms such as "needs" which seem to them more quantifiable and testable, hence more scientifically respectable. A full defense of my appeal to a concept of "caring about" should address the scientific claim; also Carruthers's arguments on this subject, and would explore some reasons why Daniel Dennett's recent account of consciousness poses a very similar threat to talk of animals' interests and caring. Although there will not be time to do justice to these themes today, they do indicate the range of serious challenges to the idea that animals do have interests and care about things.

As I have already acknowledged, terms like "interests" have a rather messy history, even within the narrow confines of debates about animals. Very roughly, with many intermediate possibilities left aside, the two opposing interpretations of "S has an interest in O" would be:

1. "S [rationally?] desires O," or
2. "O would enhance S's ability to fulfill its proper function, role, or telos."

Sense (1) is the one that leads Frey, Carruthers, and Leahy to reject the claim that animals can have full-blown morally weighty interests. Again acknowledging the oversimplification, it would seem that for all three, S's desiring O entails (a) that there is a way of specifying, fixing, or correctly identifying the object of S's desire, and (b) that S has the capacity to identify O and distinguish it from things that would not satisfy the desire.

The perhaps surprising link with Dennett comes primarily through condition (a), with (b) providing a secondary connection. Although Dennett is generally considered a supporter of cognitive ethology and its references to the intentional mental states of animals, his more recent championing of "heterophenomenology" gives a special role to language in fixing the appropriate ascription of intentional states.

A tempting, but probably misguided, response to this argument is to treat it as a variant on the problem of other minds: we can never get to the truth of what the cat wants, because the cat can't tell us in unambiguous enough terms. If we interpret the issue this way, we might be tempted to respond: "we can't tell, but the cat can, and that's what matters." This would beg the question: the charge is not simply that we cannot properly identify the object of the cat's desire, but that it cannot have any desires without a language in which to express true and false propositions about that object. The charge is that the cat lacks a medium in which to refer to or represent the object of any belief or desire, and hence cannot have beliefs and desires.

Contemporary philosophy provides a much more effective response to this concern about the possibility of having an object of belief or desire. The two salient points for our purpose, in their most general form, are: (1) any adequate psychological theory that hopes to explain animal behavior will have to attribute to many animals the ability to receive, encode, recall, and use such information; and (2) there is no reason to think that the medium in which the mind/brain encodes and manipulates information is identical with the language (if any) in which one communicates. Hence, the lack of a natural language of communication does not provide good evidence against the hypothesis that a being has a language of thought. And it is the language of thought or something analogous to it, not communication, that provides the basis for propositional attitudes.

The first of these very general ideas drawn from contemporary philosophy of mind is an essential part of a more general demonstration of why Behaviorism simply won't work. Behaviorism simply has not been able to give an adequate theory which explains the behavior of (at least) birds and mammals simply in terms of stimulus response and positive and negative reinforcements; either because the salient features for explaining the feature may not be present in the environment at the time, or because the feature is not one which can be captured in law-like statements about the environment. In marked contrast to the failures of Behaviorism, theories that work inevitably postulate that complex creatures can carry with them and access internally stored information about the world.

There are important disputes about the medium and mechanisms required to store and use information: does it have syntactic structure? how holistic is it? etc. (Even, in Dennett's case: in what sense is it real?). The relevant point of agreement for our purposes is that the medium cannot be limited to natural languages such as English. To do so (a) threatens to lead to an infinite
What Do Animals Care About?

The rust thing any self-respecting animal scientist would respond is that the demand for animals care about. Despite their lack of direct physiological or behavioral correlates or indicators (or "operant definitions"), terms like "happy" and "content" do have a justifiable place in the scientific study of animals, and they also provide a clearer foundation for investigating what animals care about.

The first thing any self-respecting philosopher would respond is that the demand for necessary and sufficient conditions was well buried with logical positivism; although we sometimes can and ought to offer such conditions, they are not always necessary for knowledge or respectable science. The undeniable fact is that experienced observers can tell quite well when an animal is happy.

On the one hand, books about dog training, horseback riding, animal husbandry of all sorts, are filled with statements like: any good dog owner (dairyman, rider, etc.) can tell whether an animal is happy, fearful, bored, or irritated. On the other hand, at some point in almost any discussion of the treatment of farm or laboratory animals, someone inevitably raises the challenge: "But you can't really give us hard scientific data about how to tell whether an animal is happy, can you?" This challenge may be followed with the assertion that it is therefore wrong to demand that we act as if a severely confined animal is unhappy (since we don't know for sure that he is), or even the charge that one is committing the eighth deadly sin: anthropomorphism.

The answer to this challenge lies in some fairly straightforward epistemology. On the assumption that we can set aside extreme skepticism (which would mean we would have to doubt not only the mental life but the physical existence of the sow and her crate, as well as the mental lives of fellow humans), there are two widely recognized reliable indications that we know what we are talking about, and that we are describing something real about the world.

The first way to convince you that I know what I'm talking about, that I'm saying something true, is to describe to you a general scientific theory and methodology that allows us to explain, predict, and understand in a fairly deep way, what is going on. If you ask me why stones roll downhill, and I glibly assure you that "it's because of gravity," you probably should probe to see whether I can back up my assertion in this sort of way. You might find out that I know no more about gravity than a nineteenth century biologist who blithely tells us that we move because of our *elan vital*.

This, of course, is the ultimate aim of science. We want to know not only what happens, but why it happens. As a result of a better understanding of why things happen, I often also get better at predicting and identifying what happens: as a result of understanding. In the case of happiness, this approach does not look very promising.

However, we often do remarkably well even in the absence of such deep explanatory theories, and we do

What Do Animals Care About?

so without lapsing into "subjectivity." All of us, to some extent, and some of us to an astounding extent, can recognize features of the world without being able to spell out in any detailed way how we do so. Here are some examples:16

(1) Chicken sexers.
(2) SAT evaluators and others who grade "standardized" essay exams.
(3) Chess players who recognize significant patterns.
(4) Any competent English speaker judging the grammaticality of sentences.

The objectivity in such cases is established in two ways. First, predictive success: the success rate of the chicken sexer can be determined quite easily, and good pattern recognizers will win more chess games. Second, where the observers are in fact picking out something that is really there, we find a high degree of intersubjective agreement, at least among skilled, trained, experienced practitioners. These two features provide good epistemic warrant for believing that observers are accurately detecting an objective feature of the world, something that is really "out there." Both features can often be found in judgments about an animal's emotional and mental states.

Predictive success in judging an animal’s inner states, including happiness, comes down to whether we can interact as we want to with animals: they do what we want, don’t attack us, settle down calmly, thrive without developing "vices," and so on. That’s why books on dog training and horseback riding are so filled with talk about the need to recognize when an animals is happy or contented. Learning to recognize these states increases one’s success at working well with the animal.

Intersubjective agreement (assuming objective, knowledgeable observers) is less obvious in the case of animal happiness because heavily influenced by preconceptions and the fact that we have been taught to talk about animals in more "rigorous" and "scientific" ways. However, if we focus on people who work and live with animals, the intersubjective agreement soon becomes apparent. Good dog handlers will usually agree about whether a dog is enjoying herself; two shepherds will pick out the same ewe as the one who is uncomfortable; and so on.

Given that reports by observers with a high degree of predictive success and intersubjective agreement are perfectly respectable sources of objective knowledge claims, and given that we have such a situation with reports about whether animals are happy, content, upset, etc., I conclude that we are justified in accepting those reports as descriptions of animals’ actual states. Having done so, we are ready to return to the topic of caring about.

Having argued that we can talk about an animal’s being happy or unhappy, and make reliable judgments about such states, I now propose to define what S cares about in terms of what makes S happy (or less unhappy) in the following manner:

S cares about O if S directly desires O, and getting or achieving O contributes to S’s happiness.

This definition entails that getting (or being denied) what she cares about makes a difference to the general state of S’s experienced well-being. It also allows for varying intensity of caring: some things will matter more than others. Finally, this definition entails that we can be mistaken about what we care about: we can think we care about something, only to discover that we were wrong: when we achieve it, we discover that it does not make us happy. These features combine to delineate a real phenomenon in many humans and many animals. The resulting definition accords well with our ordinary concept of caring about, and helps explain why the objects of caring carry moral significance in a way that more neutral interests may not.

Let me emphasize that I am not claiming that we care about things because they contribute to our happiness; we may sometimes do so, but we may have all sorts of other reasons for caring about something. Rather, I am suggesting that a hallmark, a definitive criterion of what we care about (as opposed to what we think we care about) is that it contributes to our happiness or alleviates our unhappiness.

It is, of course, beyond the scope of this paper to offer a complete axiology and to locate “what we care about” in that framework. However, at the very least, the sort of interests highlighted in this new vocabulary of “caring about” carry more prima facie moral weight than things that are merely “good for” some being. If one is a preference utilitarian, for example, caring about is a more obvious manifestation of preference than interests in any weaker sense. From a deontological perspective, paying due attention to what a being cares about seems an appropriate way of respecting the individual as a source of valuing, without reducing him/her to a mere contributor to the general good. In any
event the values highlighted by what we care about will be hard to ignore in an adequate moral theory.

In this paper, I have argued for two theses. The first is that arguments such as Frey's and Leahy's fail to establish that animals do not have interests in a morally relevant sense. The second is that we can identify the relevant sense of interests, and at least begin to illustrate its moral relevance, by focusing on the question of what animals care about. There is much more to be said on this topic, of course. The critical side of my argument must be extended to respond more specifically to other skeptics, such as Davidson and Carruthers, and potential skeptics such as Dennett. More work also remains to be done to establish the exact role in our moral theory of what beings care about. However, we have made significant progress in both these directions.

Notes

1 Tom Regan, *The Case for Animal Rights*, pp. 87-88.

3 That is, "interests" in a narrow sense, not the broad sense of interests in which something's being in S's interests reduces to that thing's being good in some way for S. The former sense has clear moral relevance for a utilitarian (especially a preference utilitarian), while the latter is unproven as a basis for moral concern. As Frey points out, tractors have interests in the broad sense, but not the narrow. (Frey, 1979, p. 233).

4 Michael Leahy, *Against Liberation*, London: Routledge, 1994, esp. Ch. 2, "R.G. Frey: The Case Against Animals." Peter Carruthers, (The Animals Issue Cambridge: Cambridge U. Press, 1992, esp. Ch 8, "Animals and Conscious Activity.") might also be placed in this camp, and there are indeed important similarities between his argument against the idea that animals can be conscious of their own mental states and the Frey/Leahy argument. However, there are also important differences that would lead too far off the topic to explore in sufficient depth.

6 I leave aside, for the sake of simplicity, the negative counterpart: S has an interest in avoiding O. The same basic analysis applies to this case.

8 *Consciousness Explained*, pp. 446-448.

9 I say "probably" for two reasons. First, this may be what some nonphilosophers are worried about. Second, at least in discussion, some of Frey's responses seem to move in this direction.

10 Although I will present the view in terminology most closely associated with Jerry Fodor's "language of thought," nothing in what I say here implies a commitment to Fodor's rejection of connectionism. Any theory which posits a method of encoding or representing information about the environment, including non-eliminativist versions of connectionism, will support the same conclusion. The two reasons presented in the text are purposely presented as claims that would be accepted by almost any plausible non-eliminativist account of cognitive states.

11 To forestall the inevitable "how far down do you go?" reply, let me point out that these systems can vary in complexity, ranging from highly abstract and complex to so simple as to no longer count as a "language of thought." For more details, see Jerry Fodor, "Why Paramecia Don't Have Mental Representations." *Midwest Studies in Philosophy*, v. X: Philosophy of Mind. French and Uehling (eds), Minneapolis: U. of Minnesota Press, 1986, pp. 3-23.

12 Two classic presentations of this sort of argument, developed in more detail, are D.C. Dennett, "Skinner Skinned," *Brainsstorms*, and Jerry Fodor, *Language of Thought*.

13 Frey may intend his analysis to provide only necessary, not sufficient conditions. However, since "desire" in his account seems to be at least one sort of real interest, "S has a desire" entails that S also has interests.

14 See note 9, above.

15 Cf. John Haugeland's famous dismissal: "The trouble with computers is that they just don't give a damn." The same thesis is developed in more depth by Fred Dretske.

16 I am purposely excluding "knowing how cases," since we are concerned with the issue of knowing that an animal is happy.

17 "Directly desire" does not mean "desire for its own sake." Rather, it is intended to distinguish those objects internally represented (as discussed above) as objects to aim at, as opposed to things which are essential to one or more of S's desires, but which S does not recognize as such. I refer to some of the latter as indirect desires. Thus, good nutrition may be essential to my dog's desire to feel good, but will at best be an indirect desire.
Response:
Straying and Spaying:
What Do Cats Care About?

William O. Stephens
Creighton University

In her paper, "What Do Animals Care About?," Lilly-Marlene Russow argues for two theses. The first is that the arguments of Frey and Leahy fail to establish that animals do not have interests in a morally relevant sense. I think she is successful in defending this thesis. Less convincing is her second thesis, namely, that we are better off focusing on the question of what animals care about than continuing to speak of the interests that animals have. While Russow's criticisms of behaviorism are persuasive, she offers no compelling grounds to accept her suggestion that computers might well have desires. Since computers lack nervous systems and are not conative organisms, it seems implausible to think they have desires. Russow is also too casual in assuming that we can simply set aside extreme skepticism. She gives no hint of how this can be done in a philosophically adequate way. But the main question I want to focus on is: What do specific nonhuman animals specifically care about?

Let me begin by reflecting in some detail on Russow's claim that "The undeniable fact is that experienced observers can tell quite well when an animal is happy." I am trained as a professional philosopher and not as a professional cat-handler, but I do fancy myself an experienced observer of feline behavior since I have lived with two cats for about thirteen years of my life. I think that for any investigation of what animals care about, it is important to address specific, concrete examples of what particular animals may or may not care about. So, now I will consider what sorts of things my cats care about.

I decided to adopt a pair of kittens about four years ago. I thought it better to have two cats rather than one since I believed that a solitary cat would be less happy than a cat with a playmate. I agree with Russow that using words like "happy" and "content" to describe nonhuman animal behavior is, though scientifically unmeasurable, still philosophically justifiable. When I went to the Omaha Humane Society to see a litter of six-week-old kittens they had told me about over the phone, I was shown a litter of four kittens, three females and a male. Since I thought I could not easily manage four growing cats, I decided to adopt the three females while hoping that someone else would adopt the male. Thus, my first decision was to separate the orphaned siblings. Did the three sisters care about being separated from their brother? All four kittens were mewing loudly at the time, which I interpreted as distress, but perhaps their distress was due to their uncomfortable surroundings at the Humane Society or the previous loss of their mother, and not their separation from their brother.

Soon after bringing the three kittens home, I tried to put small collars with their identification tags on them. They reacted by (frantically?) leaping about, arching their necks, and struggling to pull the collars off with their paws. I inferred from this behavior that they didn't much care for the collars, and so I promptly removed them. A week or two later, one of the kittens began to have diarrhea. My veterinarian diagnosed her as suffering from a gastro-intestinal infection, and he supplied me with medicine for her. Sadly, the medication failed to cure her ailment. Despite my efforts, she stopped eating entirely, became very weak in a short time, and died on a Sunday evening before I could take her to the vet the next morning. Had the unfortunate kitten stopped caring about food? Hours before she died, her two sisters huddled with her just as they had often done before when all three were healthy. Did the two surviving kittens care about their sister dying? I could not judge either way from their behavior since they neither attended closely to the dead kitten nor avoided it in any obvious way. They simply seemed to ignore it.

As is usually the case, the two cats, Bryseis and Chryseis, developed quite distinct personalities. Bryseis, the more athletic cat, exhibits a strong interest in exploring the basement, going outside, and drinking from sinks, the toilet, and the tub. Chryseis, in contrast,
seems not to care about the basement, the out-of-doors, or drinking from places other than her water bowl; Chryseis cares much more about being fed canned rather than dry cat food. Do I have a moral obligation to let Bryseis go outside? Making them wear collars as kittens seemed to make them quite unhappy. So, since Bryseis still remains collarless and untagged, I am reluctant to let her become an “outdoor” cat. If I allowed her to roam free in my neighborhood, I would expose her to the risk of fights with other animals, serious injury, or even death from being struck by an automobile. Am I justified in seriously restricting her liberty as I do?

Cats are predators, after all, and her telos as a cat certainly includes sniffing outdoor scents, stalking birds, chasing insects, and hunting small herbivores. Therefore, she might well be more content freely exploring the outdoor environment for hours every day than staying indoors all but a few minutes every week when I closely supervise her limited excursions outdoors. Does Bryseis care about living a long, safe life indoors? Or would she be much happier roaming the neighborhood unimpeded by my paternalistic, protectionist interference? Would she return home if I let her outside on her own? And if she did not, would she be happier as a stray? How am I to interpret her behavior so as reasonably to judge what would make her happiest? Would there be, to use Russow’s words, “a high degree of intersubjective agreement, at least among skilled, trained, experienced practitioners” about what would most contribute to Bryseis’ happiness?

Consider another behavior. My cats have developed the all too common “vice” of clawing the furniture, despite my conscientious efforts to trim their claws regularly. If I decided never to allow them outside on their own, then they would never need their claws to defend themselves from attack by hostile animals. Do cats care about being declawed?

Another element of the telos of cats is surely to reproduce. Do female cats care about being spayed? Are feline mothers who nurture kittens happier than their spayed sisters? Do male cats care about being neutered? Are promiscuous tomcats happier than their neutered, more docile brothers? Or do we have a paternalistic justification for spaying and neutering dogs and cats in order to minimize the number, and the usual suffering, of strays?

Russow suggests that “a definitive criterion of what we care about (as opposed to what we think we care about) is that it contributes to our happiness or alleviates our unhappiness.” Given the behavior my cats exhibit when I am away from home for long periods of time, surely they would be happier, and not just think themselves happier, were I to spend more time at home with them. Does this suffice to establish that I have a prima facie duty to spend more time at home with my cats? Russow proposes the following definition: “S cares about O if and only if S directly desires O, and getting or achieving O contributes to S’s happiness.”

This definition seems inadequate for two reasons. First, while it may seem to capture our ordinary concept of caring about inanimate objects, I think it fails to describe our ordinary concept of caring about other sentient subjects. Many humans, and perhaps many intelligent nonhuman animals as well, care about other sentient beings for their own sakes, and not only because the company of those subjects contributes to the happiness of the individual who is doing the caring. I offer the following definition of intersubjective caring:

\[ S_1 \text{ cares about } S_2 \text{ if and only if } S_1 \text{ desires to promote the happiness or well-being of } S_2, \text{ whether } S_1 \text{ and } S_2 \text{ are conspecifics or sentient beings of different species.} \]

Let us return to my stock example. Do my cats care about each other (and me) in the same sort of way that they care about being fed canned cat food and having a clean litterbox? If so, then when they play with each other they care about each other the same sort of way they care about a paper clip or a pair of socks when they play with these things. I am not inclined to construe their caring about each other so narrowly. They exhibit reciprocal altruism when they groom each other. Such reciprocal altruism suggests to me that they may well care about each other’s well-being to some extent. That is, Bryseis may well care about the subject Chryseis, an individual with her own well-being, rather than merely caring about the object Chryseis, a thing that contributes to Bryseis’ happiness.

The second reason to hesitate accepting Russow’s definition of “caring about” is that she is imposing it as a stipulative definition that does not, in fact, “accord well with our ordinary concept of caring about” even when “O” refers exclusively to objects. For example, I could on some occasion care about having some cheesecake. Later, after I find and eat a piece of cheesecake, I could well discover that having it did not make me happy but, rather, made me sad for failing to
keep to my diet. It would be wrong to say in retrospect that I didn’t really care about having the cheesecake in the first place. Rather, we should say I no longer care about having more cheesecake because, having committed dietary sin, I now care more about returning to my diet. In short, I do not see how Russow’s distinction between “caring about” and “thinking we care about” does more work than the distinction between “taking an interest in” and “successfully promoting one’s self-interest.” To say that smokers take an interest in smoking, but smoking is not really in their self-interest, strikes me as more in accord with our ordinary concepts than saying that smokers think they care about smoking, but do not really care, since smoking does not contribute to their long-term happiness. Similarly, to say that my cat Bryseis takes an interest in roaming free outside, but roaming free outside is not really in her self-interest, makes more sense to me than to say that Bryseis thinks she cares about roaming free outside, but she does not really care, since it probably endangers her long-term happiness.

Russow has made a decent attempt to advance the discussion of how best to talk about animals’ interests, desires, and happiness. However, her proposed definition of “caring about” fails to mark the qualitative difference between caring about an object and caring about a subject and does not, in fact, accord well with our ordinary concept of caring about generally. Moreover, since Russow’s discussion is deficient at the theoretical level on these points, its application to questions about specific animals—for example, whether housecats care about being allowed to stray outside, being spayed or neutered, etc.—is not promising.

I could respond by answering Professor Stephens’ specific questions about his cats: either offering a judgment about what they do and don’t care about, or explaining what one would do to determine that. But that would fill up all the remaining time, and miss his deeper concerns. Instead, I’ll say just a few words about two more general concerns that he raises, either explicitly or implicitly:

1. how we can determine the object of intentional states, including caring, and
2. why “caring about” is an improvement over talk about interests.

I take it that the philosophical issue underlying Stephens’ questions about what his cats care about in specific incidents is the concern that there may be no legitimate way of answering these questions. The full answer to his concern would be too complicated to lay out in detail—not because he’s asking about cats, but because specifying the object of any mental state is a complicated business. Nonetheless, I’ll try to indicate some of the factors that should be involved.

First, sometimes de re specifications of mental states are the most appropriate ones. That is to say, we can say that Chryseis believes of Stephens that he is a source of food, without claiming or being committed to anything about how he is “represented.” The same is true of other propositional attitudes, especially caring about. Thus, it is certainly reasonable, and perhaps even necessary, at times to read “Chryseis cares about Stephens” as a de re attitude.

Even if there is good reason to demand a de dicto account of a mental state, there still may be good
reason to suspect that we may not be able to specify the content of the state in English. First, the concepts of an individual who does not use or know English may well be different in important ways from those easily expressible in English. Indeed, given the anti-Fregean moves in contemporary philosophy of language, the so-called "narrow content" of a state may not be properly expressible in any public language. Second, when we are concerned specifically with caring about, rather than just any mental state, we are apt to conflate questions about how to specify the object of the state with the more practical issue: what would count as an adequate substitute for what is cared about, what would make the subject happy in the same sort of way. Thus, when we ask whether a cat really cares about her dead companion, we may really be trying to figure out whether introducing a new kitten would "make things right again."

As I said, these remarks only touch the surface of questions about fixing and describing the objects of care, but I hope they are in keeping with my original suggestion: current developments in philosophy of mind can help us develop a more sophisticated and more accurate way of thinking about the objects of mental states.

The second issue I want to address is the proper understanding of "care." I have proposed to analyze "caring about" in terms of two factors: desire and happiness. Thus, we can say about cats who want to go outside: they might desire to roam, but would be happier staying inside, even though they don’t realize that. The question of how we should interpret a cat’s behavior in order "to judge what would make her happiest" is misleading: the cat’s current behavior is often not the sole or even most important data about what will make her happy. Since the second condition in our definition of "caring about" refers to the future, it is possible for x to be such that it will make one happy, and thus it is possible for someone to care about x, but not know that x will make her happy, and hence not know that she cares about x. This state of affairs is even more likely to occur with nonhuman animals than with normal, adult, language using humans. It is also relevant to cases such as Stephens' cheesecake example: if eating the cheesecake did not, in fact, contribute to his happiness (i.e., he eats the cheesecake and is no happier afterwards—perhaps even feels disappointed), I would argue that, even though he wanted or desired the cheesecake, he was simply mistaken in thinking

that he cared about it. If we tell the story slightly differently (eating one small slice of cake made him happy, given that he was able to return to his diet), then we should conclude that he cares about eating cheesecake in moderation.

Proper attention to the details of my proposal is also relevant to Stephens' suggestion that my proposed analysis of caring fails to do justice to caring for other subjects. I explicit denied the claim that we care about things because they contribute to our happiness. If we avoid that mistake, I fail to see how caring for other subjects falls outside my account.

I can only briefly mention two other points Stephens brings up. First, does the fact that S cares about x engender a prima facie duty to ensure that S obtains x? The short answer is that my account was not intended to give a complete answer, although I will point out that we do hold people morally culpable for neglecting animals for whom they are responsible. Second, he objects to my claim that computers might have desires on the grounds that they don't have nervous systems. This seems to me to beg the question against artificial intelligence in particular, and functionalist accounts of mind in general.
